(57) **ABSTRACT**

A computer system includes a display interface; a user input device interface; and a processor cooperatively operable with the display and user input device interfaces. The processor provides a browser user interface that interacts with a user to selectively indicate (i) content fields displayed in the source user interface from which information is to be sent and (ii) content fields displayed in the destination user interface which are to receive the information from the source content fields. The computer system stores an indication of the destination app registered for the topic together with an indication of the selected destination content fields which are to receive the information from the selected content fields of the source app. The source app and destination app do not publish/subscribe to each other. An intermediary brokers messages from the source app, maps the data, and sends on to the destination app.

METHOD AND SYSTEM FOR VISUAL WIRING TOOL TO INTERCONNECT APPS

CROSS-REFERENCE TO RELATED APPLICATIONS

This application claims the benefit of the following Provisional application: 61/351,367 filed Jun. 4, 2010, which is expressly incorporated herein by reference.

TECHNICAL FIELD

The technical field relates in general to computer networks, and more specifically to apps and sharing data in apps.

BACKGROUND

Conventionally, a developer must write custom code to send information from one app to another. A less technically savvy user cannot interconnect apps.

For example, OpenAjax Hub 2.0 provides publish/subscribe services that enable script logic (from libraries, components and the application itself) to publish events on a broadcast basis and to listen (i.e., subscribe) to events fired by other script logic. However, this requires the ability to code the script logic into the publisher/subscriber apps.

SUMMARY

Accordingly, one or more embodiments provides a computer system, a computer-readable non-transitory medium, and/or a method. The embodiments can provide for a client computer system comprising a display interface; a user input device interface; and a processor. The processor is cooperatively operable with the display interface and the user input device interface, and configured to facilitate providing a browser user interface that simultaneously displays on a single page via the display interface, a destination user interface of a destination app, a source user interface of the source app, and a topic; interacts with a user, via the user input device interface, to selectively indicate on the browser user interface (i) content fields displayed in the source user interface from which information is to be sent and (ii) content fields displayed in the destination user interface which are to receive the information from the content fields in the source user interface. The processor also stores, in a container storage, an indication of the destination app as being registered for the topic together with an indication of the selected content fields of the destination app which are to receive the information from the selected content fields of the source app, whereby the source app and the destination app do not need to be known to each other and are wired together at the container storage.

The embodiment can include running the destination app via the display interface; and receiving a message from an intermediary processor instead of from the source app, the message having destination information input to the destination app, so that publication caused by a change to the information at the source app triggers a reaction in the destination user interface displaying the information at the destination app.

Another embodiment provides a browser user interface that simultaneously displays on a single page a plurality of topics which are published each having a source app, and interacts with a user to select at least one destination app to register for at least one of the plurality of topics.

2

Another embodiment provides a browser user interface that simultaneously displays on a single page a plurality of topics which are published each having a source app and at least one registered destination app, and interacts with a user to select one or more of the topics to be disabled from publishing.

According to another embodiment there is provided an intermediary computer system, comprising a container storage; and an intermediary processor cooperatively operable with the container storage. The processor is configured to facilitate: providing, in the container storage, an indication of a topic, an indication of a source app that publishes information regarding the topic, an indication of a destination app registered for the topic to receive the information, and a property mapping indication of how the information to be sent from the source app maps to destination information displayed at a destination user interface of the destination app; receiving, at the intermediary processor instead of at the destination app, a published message from the source app, the published message including the information sent from the source app and not property-mapped according to the property mapping in the container storage; and obtaining, at the intermediary processor from the container storage, the indication of the destination app registered for the topic, and then sending from the intermediary processor to the destination app registered for the topic the published message with the information which has been property-mapped as destination information according to the property mapping in the container storage, when the published message includes the topic with the registered destination app stored on the container storage, so that publication caused by a change to the information at the source app triggers a reaction in the destination user interface displaying the information at the destination app.

Another embodiment includes mapping, at the intermediary processor, the information in the published message received from the source app according to the property mapping in the container storage and sending to the destination app a destination message with the information which has been property-mapped as destination information. The mapping can omit a portion of the information, recast at least a portion of the information to a different data-type, extract of at least a portion of the information, perform a calculation on the information, perform a string manipulation on the information, augment the information, so as to conform information that is not compatible as-is from the source app to the content fields displayed at the destination user interface which are to receive the information.

According to another embodiment, receipt of the message at the intermediary processor and publication of the message from the intermediary processor is performed in accordance with OpenAjax Hub standards.

In another embodiment, there is provided an intermediary computer system acting as a server, and a client computer system that is running the registered destination app as a client and further that is cooperatively connected to and in communication with the server. The intermediary processor coordinates receipt by the client of messages published from the source app having information for the topic listing the registered destination app stored on the container storage.

There can also be a computer-implemented method, implemented on a computer system, for visual wiring of apps. The method can include providing, in a container storage, an indication of a topic, an indication of a source app that publishes information regarding the topic, an indication of a destination app registered for the topic to receive the information, and a property mapping indication of how the infor-

mation to be sent from the source app maps to destination information displayed at a destination user interface of the destination app; receiving, at an intermediary processor instead of at the destination app, a published message from the source app, the published message including the information sent from the source app and not property-mapped according to the property mapping in the container storage; and obtaining, at the intermediary processor from the container storage, the indication of the destination app registered for the topic, and then sending from the intermediary processor to the destination app registered for the topic the published message with the information which has been property-mapped as destination information according to the property mapping in the container storage, when the published message includes the topic with the registered destination app stored on the container storage, so that publication caused by a change to the information at the source app triggers a reaction in the destination user interface displaying the information at the destination app.

Still another embodiment provides for a non-transitory computer-readable medium storing computer-executable instructions that provide the method when executed.

Still other embodiments provide for a method for the foregoing, and/or a non-transitory computer-readable medium with instructions thereon which, when executed, perform the foregoing.

Further, the purpose of the foregoing abstract is to enable the U.S. Patent and Trademark Office and the public generally, and especially the scientists, engineers and practitioners in the art who are not familiar with patent or legal terms or phraseology, to determine quickly from a cursory inspection the nature and essence of the technical disclosure of the application. The abstract is neither intended to define the invention of the application, which is measured by the claims, nor is it intended to be limiting as to the scope of the invention in any way.

BRIEF DESCRIPTION OF THE DRAWINGS

The accompanying figures, where like reference numerals refer to identical or functionally similar elements and which together with the detailed description below are incorporated in and form part of the specification, serve to further illustrate various exemplary embodiments and to explain various principles.

FIG. 1 is an example user interface.

FIG. 2 is a second example user interface.

FIG. 3 is a portion of the second example user interface illustrating a top level summary.

FIG. 4 is a portion of the second example user interface illustrating Step 1, Select Target/Subscriber App.

FIG. 5 is a portion of the second example user interface illustrating Step 2, Select Source/Publisher App.

FIG. 6 is a portion of the second example user interface illustrating Step 3, Topic Mapping/Transformation.

FIG. 7 is a block diagram illustrating a message format.

FIG. 8 is a block diagram illustrating portions of a client computer system and an environment thereof.

FIG. 9 is a block diagram illustrating portions of an intermediary computer system and an environment thereof.

FIG. 10 is a flow chart illustrating a process for visual wiring of apps.

DETAILED DESCRIPTION

In overview, the present disclosure concerns computer systems, sometimes referred to as client/server networks, such as

may be associated with computer systems providing apps. Such computer systems often involve running an app on a user's computer that invokes a web service providing live data. More particularly, various inventive concepts and principles are embodied in systems, devices, and methods therein for interconnecting apps and especially for communicating data from one app to another.

The computer systems of particular interest are those providing or facilitating apps over communication networks involving a data server and a user's computer, and the like, and variants or evolutions thereof.

The instant disclosure is provided to further explain in an enabling fashion the best modes of performing one or more embodiments. The disclosure is further offered to enhance an understanding and appreciation for the inventive principles and advantages thereof, rather than to limit in any manner the invention. The invention is defined solely by the appended claims including any amendments made during the pendency of this application and all equivalents of those claims as issued.

It is further understood that the use of relational terms such as first and second, and the like, if any, are used solely to distinguish one from another entity, item, or action without necessarily requiring or implying any actual such relationship or order between such entities, items or actions. It is noted that some embodiments may include a plurality of processes or steps, which can be performed in any order, unless expressly and necessarily limited to a particular order; i.e., processes or steps that are not so limited may be performed in any order.

Much of the inventive functionality and many of the inventive principles when implemented, are best supported with or in software or integrated circuits (ICs), such as a digital signal processor and software therefore, and/or application specific ICs. It is expected that one of ordinary skill, notwithstanding possibly significant effort and many design choices motivated by, for example, available time, current technology, and economic considerations, when guided by the concepts and principles disclosed herein will be readily capable of generating such software instructions or ICs with minimal experimentation. Therefore, in the interest of brevity and minimization of any risk of obscuring the principles and concepts herein, further discussion of such software and ICs, if any, will be limited to the essentials with respect to the principles and concepts used by the exemplary embodiments.

As further discussed herein below various inventive principles and combinations thereof are advantageously employed to facilitate a means for an app to receive published data without re-programming the app to insert hand-shaking about the topics that may be published and how to react to different topics. Apps conventionally publish topics. However, conventionally there has been no easy way for an ordinary user to wire the data from an app to be requested by and received specifically by another app. The following disclosure provides various principles that disclose how to broker the published information so it can be used by a pre-existing app without programming the app to specifically receive topics from the source app that provides the information. Setting up the intermediary broker via a simple user interface provides a visual wiring metaphor which is easy for an ordinary user to manipulate.

Overview

Referring now to FIG. 1, an example user interface 101 will be discussed and described. The event wiring capability allows for interconnecting one or more apps 105, 107, 109, 111, 113 to orchestrate functional and behavioral dependency between apps and build an event-driven interconnected app 113. When one or more apps are wired, initiating an action on

5

one app (source) can trigger reactions from the connected apps (target). The target apps in turn could initiate other events in response which could lead to additional changes. Event wiring can be persisted within an applicable app container to permanently store the dependencies.

Here, there is a single screen **103** on which are displayed apps **105**, **107**, **109**, **111**, **113**, for example on a dashboard, and each of the apps is focused on different information. (An app can be thought of as a way to visualize a mashup.) A topic viewer app **105** lists topics **129** to which a destination app can subscribe. Destination apps which receive information (typically from a data service or as specified by interaction with a user) in this example include MashupGridView **111** which populates a grid with data, the number of rows and columns matching the amount of incoming information; a ChartView app **107** provides a bar chart with a labels on the x-axis, and quantities on the y-axis; and a GoogleMap app **113** provides a map with pushpins indicating latitude/longitude of various geographic locations. A ServiceInvoker app **109** lists available source apps that publish information as data services, in this example, an app **127** that provides data on “active volcanoes” and listing the data from the service **125**: “id, name, lat, long”.

As later described, the user can interact with the user interface **101** (sometimes referred to as a “source-destination-browser user interface”) (e.g., via the ServiceInvoker **109**) to indicate that one of the source apps should publish data specifically to one or more of the destination apps **107**, **111**, **113**. Then, the destination apps receive the information and display the information. Since the Active Volcanoes **127** source app publishes information on ID, name, lat and long, the MashupGridView destination app **111** does what it usually does and populates the information into a grid, resulting in a list of volcanoes, more particularly, the information is provided, in the illustrated columns, as ID, name, lat (latitude) and long (longitude). However, the published information is more than can be used by ChartView and GoogleMap. Here, the ChartView app **107** is a destination app and receives **119** “Name” and “lat” information only and accordingly displays only that information as “label” and quantity. Here, the GoogleMap app **113** is a destination app and receives **117** only “long” and “lat” and displays pushpins **115** at the input longitude and latitude.

In this example, the app ServiceInvoker **109** is sending a message **123** to the app TopicViewer **105**. Also, the user can select MashupGridView **111** as a receiver to receive a message **121** from ServiceInvoker **109** as the sender.

Then, the user can map the parameters that come in from the message from the sender to what the receiver’s parameters are.

Then, when the user clicks the “Submit” button on ServiceInvoker app **109**, the TopicViewer **105** is updated (due to the change of data in the source app **109**) and the MashupGridView destination app **111** displays are updated. ServiceInvoker **109** is a source app that is wired as a sender to destination apps **105**, **111** TopicViewer and also to MashupGridView which are receivers.

Then, for example, the user can click the wiring button, to wire ServiceInvoker **109** as a source app to a different destination app, that is, ChartView **107**. Then, the user can map the ServiceInvoker and ChartView parameters, and click the “Finish” button. The destination app behaves as usual upon receiving the information from the source app. Consequently, the user can create the wiring between the source and destination app via the user interface, without adding further instructions to the destination app to specifically receive information from the source app.

6

As another example, a user can wire the GoogleMap app **113** as a destination app to receive a message from the ActiveVolcanoes app, as follows. The user can select a row in MashupGridView **111**. The system can be wired to use the ID and the label (parameters in the selected row) in MashupGridView to set an item in the ChartView app **107**. The system can be wired to use the latitude and longitude (parameters in the selected row) to set a pushpin on the GoogleMap app **113**.

App Event Wiring Tool

App event wiring can be performed using a visual wiring tool that allows users to browse and inspect the available event topics and connect one or more of them to suitable a target app, simply through the visual interface. Apps can publish multiple events and multiple apps can be connected to single app event. The visual wiring tool can support event message transformation to connect apps that may not be compatible as-is. Event message transformation can connect apps from different vendors or user groups.

Referring now to FIG. **2** to FIG. **6**, a second example user interface **201** (sometimes referred to as the “source-destination-browser user interface”) will be discussed. FIG. **2** is a second example user interface. FIG. **3** is a portion of the second example user interface illustrating a top level summary to set up the visual wiring. FIG. **4** is a portion of the second example user interface illustrating Step **1**, Select Target/Subscriber App. FIG. **5** is a portion of the second example user interface illustrating Step **2**, Select Source/Publisher App. FIG. **6** is a portion of the second example user interface illustrating Step **3**, Topic Mapping/Transformation.

User Interface

The user can invoke the app wiring menu by clicking an app wiring menu button **217**, e.g., FIG. **2**. This brings up a screen with a list of options and can prompt the user to select the receiver of the message and the sender of the message, e.g., FIG. **3**. In the example of FIG. **2**, the app Grid **203** is sending a message **211** to the app GetTopicsByExchange **205**. Also, the user can select GetDividendHistory app **209** as a receiver to receive a message **215** from GetTopicsByExchange **205** as the sender. Also, the user can select the app MarketIndices **207** as a sender to send a message **213** to the destination app GetTopicsByExchange **205**. In this example, a wiring menu (see FIG. **3** to FIG. **4**) is invoked by selecting a button **217** on one of the apps the user interface **201**. Then, the user can map the parameters that come in from the message from the source app to the parameters of the destination app.

Referring now to FIG. **3** to FIG. **6**, steps for a user interface to set up wiring between a source app and a destination app will be discussed and described. In FIG. **3**, the user has invoked a message wiring menu **313** by selecting the app wiring menu button **311**. FIG. **3** illustrates a user interface **301** with apps ListTopExchanges **303**, GetTopicsByExchange (in the drawings, “GetTopsByExchange”) **305**, MarketIndices **307**, and DividendHistory **309**. The message wiring menu **313** can list subscriptions, and they can be filtered by the app that sends the subscription and/or the topic of the subscription. The message wiring menu **313** can list pairs of source app/destination app that are wired together, i.e., with the destination app already set to receive information which is a topic published by the source app. Here, a first visual wiring pair **315** is ListTopExchanges as a source app sending the topic Grid.rowclick.ListTopExchanges to the destination app GetTopicsByExchange (in the drawings, “GetTopsByExchange”); and a second visual wiring pair **317** is MarketIndices as a source app sending the topic DoughnutChartElement.MarketIndices to the destination app GetTopicsByExchange (in the drawings, “GetTopsByEx-

change”). As shown in FIG. 4 to FIG. 6 (discussed in more detail below), from this menu a user can select a subscriber and a destination and set up mapping of information to be provided from the subscriber to the destination.

Then, now referring to FIG. 6, when the user clicks the “save & continue” or “finish” button on App-to-App Message Wiring menu 601, the source app is wired as a sender and the destination app is a receiver.

The app wiring menu can conveniently display all the current wiring and a user can disable one or more wiring by unselecting the publisher.

Consequently, the system can set up or disable eventing or messaging between two of the apps on the page.

Thus, a UI is provided with a visual display of the wiring so that a business analyst or end user (not a programmer) can accomplish the sending of information between two apps without writing custom code. The visual wiring metaphor that is provided can connect up information between these different artifacts on the page.

Mapping Incoming Parameters

Referring again to FIG. 1, in MashupGridView, a user can click on one of the displayed rows to send information from that row to a couple of the other apps on this page, namely, to ChartView and to GoogleMap. In the ChartView, for example, a user can have the label in the ChartView chart to use the information in the MashupGridView name columns and the value of the ChartView chart to use any numeric column from the MashupGridView. Also, a pushpin can appear on the GoogleMap when it receives the MashupGridView Lat and Long information (mapped to GoogleMaps latitude and longitude parameters) which is used to put the pushpin in the map. So the information can be visually wired by interacting with a user, so as to map the parameters for the data that is passed from one app to the other app.

Also note, in this example, a user selected a row of information (to pass to an app) that has four parameters, but the apps to which the parameters are passed only have two parameters. In the GoogleMap app there is no parameter that maps to the parameter in the sender called Name or ID, but these incoming parameters can be ignored in favor of the incoming parameters called “Lat” and “Long” which are mapped to the “Latitude” and “Longitude” parameters on the receiver, respectively.

Then, eventing can occur, for example according to known techniques. The destination app as it exists, for example, may choose to replace all information, or add to existing content when it receives information via the eventing. In the case of the ChartView app, it might add a bar. A different app might behave differently, according to how it is programmed. The point is that the destination app need not be re-programmed to accommodate the visual wiring, but the destination app, when executing, expects to receive data; one type of expected data in some apps (if present) can cause the destination app to initialize existing content, or to simply add newly received information to existing content.

Each of the apps (source app or destination app) can be a conventional app. A technique for eventing (transmitting information from one app) is conventional. In “eventing”, an app fires an event, which causes a message to be published, for example, via OpenAjax Hub. The eventing can be a peer-to-peer passing of an event from the source app to the intermediary, and then from the intermediary to the destination app.

Previously, the code for passing the information had to be programmed by developer. In accordance with this disclosure, a technically less savvy person can generate the code using this visual wizard, (1) to attach the code to generate an

event (which is targeted to the receiving app) to the apps that have registered interest in receiving events (eventing code is known); and (2) to attach code to receive the event (eventing code is known), and when the event is received from that app to map the incoming parameters to the parameters which the receiving app uses. As discussed later in more detail, the code added at an intermediary rather than at the destination app or source app.

“App” can refer to a single-purpose-type widget instead of a large overarching application.

Reference is now made again to FIG. 1.

The UI 101 of FIG. 1 illustrates setting up eventing or communication or data passing from one of the illustrated apps to others. E.g., in ServiceInvoker, when “Submit” is clicked, the user wants to pass information from ServiceInvoker 109 as a source app to TopicViewer 105 and to MashupGridView 111 as destination apps.

In this case, TopicViewer 105 shows the entire message 123 which was passed, in a raw form. MashupGridView 111 uses that to make a call to an app using the information 121 from ServiceInvoker 109.

A more typical example is to map parameters from, e.g., MashupGridView 111 as a source app to ChartView 107 as a destination app. Here, the “Name” and “ID” parameters in MashupGridView are mapped to the “Label” and “Value” parameters (respectively) in ChartView. Similarly, the Lat and Long parameters from MashupGridView are mapped to latitude and longitude parameters in GoogleMaps 113 as a destination app.

There is a known framework which can be used to execute the eventing, e.g., available from the OpenAjax client, e.g., OpenAjax Hub 2.0 (specified in the OpenAjax Hub 2.0 Specification), and variants and evolutions thereof.

Reference is now made to FIG. 4, a portion of the second example user interface illustrating Step 1, Select Target/Subscriber App. In FIG. 4, there is illustrated an app-to-app message wiring menu 401, a destination app menu 403 to select the subscriber app, a list of subscriber names (destination app candidates) 405 (in the drawings, “Subscriber App”), a list of subscription topics (topic candidates) 407, an indication of the selected destination app 409, and a visual wiring display showing the name of the selected destination app 411. The arrow going into the destination app 411 visually indicates that the named destination app 411 will receive the information. To select a target/subscriber app, in this example, the UI wiring menu 401 shows the available apps 405, and the user selects one 409 as the target (to receive the information).

Reference is now made to FIG. 5, a portion of the second example user interface illustrating Step 2, Select Source/Publisher App. In FIG. 5, there is illustrated an app-to-app message wiring menu 501, a publisher topic menu 503 to select the subscriber app, a list of names of published topics (topic candidates) 505, a list of publisher names that correspond to the topics (source app candidates) 507, an indication of whether mapping is required between the destination information and the source information of that publisher (that is, when there is not a one-to-one correspondence between information), an indication of the selected published topic and source app 511, and a visual wiring display showing the name of the selected source app 513 (in the drawings, “GetTops-ByExchange”) and destination app 515. In this example, both the source app and destination app have been selected, and whether or not the source information and destination requires mapping can be automatically determined by whether there is a one-to-one correspondence between source and destination information; the user interface can show an

indication when mapping is required. The arrow going into the destination app **411** visual indicates that the named destination app **411** will receive the information. To select the source/publisher, a menu **503** shows the available topics **505** and/or apps **507**, and the user selects one **511** as the publisher (to send the information).

Reference is now made to FIG. 6, a portion of the second example user interface illustrating Step 3, Topic Mapping/Transformation. In FIG. 6, there are illustrated an app-to-app message wiring menu **601** and a publisher-to-subscriber topic mapping menu **603**. To select the mapping of the parameters, the parameters of the publisher and the source are presented to the user, so the user can select the mapping of (1) which source parameter is received into which destination parameter, and (2) operations to transform the source parameter before being used as the destination parameter. Here, the publisher parameters are displayed on the left hand column (in this example, "username", "password", "tracer", "identifier", and "identifiertype"). There is a drop down menu **605**, **607**, **609**, **611**, **613** for each of the publisher parameters listing the subscriber/target parameters; see the drop down menu **613** for "IdentifierType" which lists each of the destination parameters, here "name", "symbol", "last", "exchange", "change", "volume," and "PercentChange". To indicate which source parameter is received into which destination parameter, the mapping menu **603** interacts to prompt the user to manually select one of the subscriber/target parameters **613** to match to one of the publisher parameters. There does not need to be a one-to-one mapping of parameters, that is, source parameters or publisher parameters can be omitted.

The names which are displayed for the source and destination parameters are the names of the content fields. The information will be supplied from the content fields with the selected names in the source, and the information will be used as content in the content fields with the selected names in the destination as indicated in the publisher to subscriber mapping. Content fields can be omitted.

Optionally, information can be transformed before being provided to the destination. An additional menu can be provided to specify a change of parameter type (e.g., numerical to text), to augment information, to execute a calculation on information (e.g., to change percent to ratio), and the like.

Referring now to FIG. 7, a block diagram illustrating a message format will be discussed and described. In this example, a message **701** can include a topic **703** (as the message header) and a payload **705**. The topic **703** specifies a string name describing the published message, generally prefixed by the app name followed by a ".". The payload **705** holds the data payload of the message, typically the app name, properties of the data, and the data itself as determined by the publisher of the message. A further description of the format and message passing conventions and conventions for names of topics according to some embodiments can be located in the OpenAjax 2.0 specification. According to some conventions, a topic name can embed a name of the source of the message. A message **701** can be broadcast from a source app, for example by invoking an available publish feature. A message **701** can be subscribed to by invoking an available subscribe feature.

According to OpenAjax, a publisher will publish a message when a new event occurs, e.g., whenever data is changed. The message can be broadcast—a publisher can be unaware of who the subscribers are or how many subscribers there are. According to OpenAjax, a subscriber that wants to be notified whenever an event occurs includes executable program code (1) first to subscribe to the event and (2) next to do something in response to the event and its data when received.

As described further herein, there is no need for a destination app to subscribe to the event. The source app publishes the message **701** as usual; an intermediary is subscribed to the topic published by the source app and receives the published message **701**. Then, the intermediary performs any specified source-to-destination mapping to the information carried in the payload **705** of the message **701**, before sending the mapped information to the destination app. If the destination app can receive a message **701**, the information can be sent in a message; if the destination app expects to receive information as data provided by an information service such as a web feed format, e.g., RSS (really simple syndication), the information can be sent in the standardized format expected by the destination app, e.g., RSS format.

Referring now to FIG. 8, a block diagram illustrating portions of an exemplary client computer system and an environment thereof will be discussed and described. The computer system **801** may include a communication port and/or transceiver **803** or the like for communication with an intermediary, e.g., a server **847**, a processor **805**, a memory **807**, a display interface **833**, a display **835**, an input interface **837**, and/or a user input device **839** such as a keyboard, trackball, mouse, joystick, pointing device, and/or similar.

The server **847** can be a part of a platform comprising the server **847** and a client app which can execute on the processor **805** of the computer system **801**. Server and client functions can be distributed between the server **847** and the client app according to known techniques. The client app on the client computer system **801** can invoke one or more web services as an information-providing services as is known to obtain data from a data source.

The illustrated communication port/transceiver **803** is representative of one or more receiver and/or transmitter and/or transceiver communication ports, for wired or wireless communication, over a computer network or communication network.

Also, the intermediary (server) **847** can access a container storage **849** on which topics can be stored, each topic indicating a source app (here represented by source app **841**) that publishes the topic as a published message **843** and one or more destination apps which have registered to receive the topic and a property-mapping from source information to destination information so that the intermediary (server) **847** can send a property-mapped message **845** with property-mapped information. The container storage **849** can be a database.

The processor **805** may comprise one or more microprocessors and/or one or more digital signal processors. The memory **807** may be coupled to the processor **805** and may comprise a read-only memory (ROM), a random-access memory (RAM), a programmable ROM (PROM), and/or an electrically erasable read-only memory (EEPROM). The memory **807** may include multiple memory locations for storing, among other things, an operating system, data and variables **809** for programs executed by the processor **805**; computer programs for causing the processor to operate in connection with various functions such as to provide **811** a browser user interface that interacts with the user to set up source-destination wiring, get **817** list of available topics, register and store **819** a registered destination app and wiring, receive **821** a message with info for destination app, provide **823** a browser user interface that displays published topics and selects or disables topics accordingly, a destination app user interface/destination app **827**, a source app user interface/source app **829**, and/or other processing; and a database **831** for other information used by the processor **805**. The computer programs may be stored, for example, in ROM or

PROM and may direct the processor **805** in controlling the operation of the computer system **801**. Each of these functions is considered in more detail below.

The user may invoke functions accessible through the user input device **839**, interface with the processor **805** through an input interface **837**. The user input device **839** may comprise one or more of various known input devices, such as a keyboard and/or a pointing device, such as a mouse; the keyboard may be supplemented or replaced with a scanner, card reader, or other data input device; the pointing device may be a mouse, touch pad control device, track ball device, or any other type of pointing device; and the input interface **837** can be a known interface thereof to communicate with the processor **805**.

The text and/or image display **835** is representative of a display that may present information to the user by way of a conventional liquid crystal display (LCD) or other visual display, and/or by way of a conventional audible device for playing out audible messages. The display interface **833** can be a known interface thereof to communicate between the processor **805** and the display **835**.

Responsive to signaling from the user input device **839**, in accordance with instructions stored in memory **807**, or automatically upon receipt of certain information via the communication port and/or transceiver **803**, the processor **805** may direct the execution of the stored programs.

The processor **805** can be programmed to provide **811** a browser user interface (sometimes referred to as the "source-destination-browser user interface") that interacts with the user to set up source-destination wiring, as described above in much detail. The browser user interface interacts with the user to select, as a source app, one of the source apps that publishes information. The browser user interface also interacts with the user to select, as a destination app, an app that can receive information for examples information sent from a data service. Candidate names of destination apps can be obtained from apps which are known to the client computer system **801** as available apps in accordance with known techniques. The browser user interface can display, simultaneously, for example on a single screen, and/or in a same window, the destination app user interface (or name(s) thereof) and the source app user interface (or name(s) thereof) and the topic(s) which are published. The browser user interface can obtain the names and descriptions of the content fields of the source app from which information is to be sent and of the destination user interface which are to receive the information. In the event that there is not a perfect relationship between the respective content fields (i.e., the number of fields differs or the type of content of the fields differs), the user interface can interact with the user to select which source fields go to which destination fields and also to determine manipulations which are to be performed on the source information before being sent to the destination app.

The processor **805** can be programmed to get **817** list of available topics, that is, the topics which are published, and/or the apps which provide published messages. The list can be retrieved by transmitting a message requesting the list to the intermediary (server) **847** from the client computer system **801**; and by receiving a message listing the topics and/or apps, optionally with registered destination apps and property mapping information. The intermediary (server) **847** can be programmed, upon receipt of a message requesting such a list, to retrieve a list of topics and associated source apps and so forth from the container storage **849**. Such a list can be used to support the browser user interface **811** that displays the available source apps and topics.

The processor **805** can be programmed to register and store **819** an indication of a destination app as registered for the topic from the source app, with an indication of the selected content fields of the destination app that are to receive information from selected content fields of the source app, as well as any property mapping between the respective source and destination content fields. The processor **805** can collect the information, for example, via a browser user interface **811** that interacts with the user to set up the app wiring, and can store the app wiring by transmitting a message sending the app wiring information to the intermediary (server) **847** to be stored in the container storage **849**.

The processor **805** can be programmed to receive **821** a message with information for the destination app **827**. The destination app **827** can be set up, according to conventional app techniques, to receive data or to retrieve data. The message with information for the destination app can be the message **845** sent from the intermediary (server) **847** that has the property-mapped information. The destination app **827** can accept the information without discriminating the source of the information. Accordingly, the destination app **827** will handle the message with the property-mapped info the same as it handles its usual data.

The processor **805** can be programmed to provide **823** a browser user interface that displays **825** published topics and select or disable topics accordingly. The browser user interface **823** can simultaneously display topics which are published by one or more source apps (e.g., in a list), can select one or more of the destination apps to be registered for one of the topics that is published, and/or can set one or more of the published topics to be disabled from publishing.

The list of available topics can be obtained by sending a message with a request for the list to the intermediary (server) **847** and receiving the list therefrom.

The browser user interface **823** can interact with the user to select one or more of the destinations apps to be registered to receive information from one or more of the listed available topics. The registered destination and topic, along with any property mapping, can be sent to be stored **819** in the container storage.

One or more of the published topics can be sent in a message with a request to be disabled to the intermediary (server) **847**, which can temporarily mark the topic in the container storage **849** as being disabled. When the intermediary (server) **847** receives a published message **843** for a disabled topic, the intermediary **847** can omit to send the message with the information **845** to the client computer system **801**.

The processor **805** can be programmed with a destination app user interface/destination app **827**, and/or with a source app user interface/source app **829**. An app can be set up using known techniques to broadcast a message, usually when an event occurs such as when data (which likely is displayed) is added, deleted or modified. An app conventionally can be set to receive the data or to retrieve the data from a server without interfering with the display of the existing page, with the retrieved data to be displayed such as on the existing page. Conventional techniques for doing so include AJAX and similar web applications. Typically, according to conventional techniques, the client side of the app provides a user interface; a server side of the app may be provided, for example on a remote server.

The computer system **801** discussed here or elsewhere in this document can include a central processing unit (CPU) with disk drives (not illustrated), symbolic of a number of disk drives that might be accommodated by the computer. Typically, these might be one or more of the following: a floppy disk, a hard disk, a CD ROM, a digital video disk, an

13

optical disk, a removable flash memory, or the like, or variations thereof. The number and type of drives may vary, typically with different computer configurations. Disk drives may be options, and for space considerations, may be omitted from the computer system used in conjunction with the processes described herein. The computer may also include a CD ROM reader and CD recorder, which are interconnected by a bus along with other peripheral devices supported by the bus structure and protocol (not illustrated). The bus can serve as the main information highway interconnecting other components of the computer, and can be connected via an interface to the computer. A disk controller (not illustrated) can interface disk drives to the system bus. These may be internal or external.

It should be understood that FIG. 8 is described in connection with logical groupings of functions or resources. One or more of these logical groupings may be omitted from one or more embodiments, for example, the functionality of providing 811 a browser user interface that interacts with the user to set up source-destination wiring, can be omitted and/or performed on a different processor from the functionality of the browser user interface 823 that registers 825 for topics and/or disables from publishing, which can be provided on a different processor than the destination app user interface/destination app 827 and/or source app user interface/source app 829. Likewise, functions may be grouped differently, combined, or augmented without parting from the scope. Similarly the present description may describe various databases or collections of data and information. One or more groupings of the data or information may be omitted, distributed, combined, or augmented, or provided locally and/or remotely without departing from the scope.

Referring now to FIG. 9, a block diagram illustrating portions of an intermediary computer system and an environment thereof will be discussed and described. The computer system 901 may include a communication port and/or transceiver 903 or the like for communication, e.g., with a computer such as client 935 or source app 929 running on another computer; a processor 905, and a memory 907; a display and/or an input device may be included or omitted. Other portions are not omitted from the present discussion because they are well understood in this field.

The communication port/transceiver 903 is representative of one or more receiver and/or transmitter and/or transceiver communication ports, for wired or wireless communication, over a computer network or communication network.

Also, the computer system 901 can access a container storage 937 on which topics 939, 941, 942 can be stored, each with an indication of a source app that publishes the topic, a registered destination app, and any property mapping. The source app, here represented by source app 929, publishes the topic as a published message 931 that can be broadcast in accordance with known techniques to any app that is listening for published broadcast messages. The computer system 901 can receive the published (broadcast) message 931 at the transceiver 903. The computer system 901 can send a message 933 from the transceiver to a client computer system running a destination app 935. The container storage 937 can be a database.

The processor 905 may comprise one or more microprocessors and/or one or more digital signal processors. The memory 907 may be coupled to the processor 905 and may comprise a read-only memory (ROM), a random-access memory (RAM), a programmable ROM (PROM), and/or an electrically erasable read-only memory (EEPROM). The memory 907 may include multiple memory locations for storing, among other things, an operating system, data and

14

variables 909 for programs executed by the processor 905; computer programs for causing the processor to operate in connection with various functions such as to receive 911 a message with source information, determine 913 whether the message includes a topic with a registered destination app, obtain 915 an indication of the registered destination app for the received message, send 917 the message with the property-mapped destination information to the registered destination app, get/send 919 a list of available topics, provide 921 a browser interface for the client computer to set up visual wiring, store 923 the registered destination app in the container storage, map 925 source information in the published message, and/or other processing; and a database 927 for other information used by the processor 905. In accordance with instructions stored in memory 907, upon receipt of manual instructions from an input device (not illustrated), or automatically upon receipt of certain information via the transceiver 903, the processor 905 may direct the execution of the stored computer programs, and the computer programs may direct the processor 905 in controlling the operation of the computer system 901 to perform functions. Each of these functions is considered in more detail below, although details which have been discussed previously may be omitted to avoid redundancy.

The processor 905 can be programmed to receive 911, via the transceiver 903, a message with source information from the source app 929 which is listed in the container storage 937, in accordance with available techniques for receiving messages. For example, the processor can be set to receive all broadcast messages or message regarding topics listed in the container storage 937, such as via OpenAjax Hub subscribe API or similar, variations and extensions thereof. The source app 929 is set to send messages when data therein is added or updated, for example, by anonymously broadcasting messages or passing messages instead of using point-to-point message, for example using OpenAjax Hub publish API, extensions and variations thereof. The source app 929 does not send the message to the destination app 935 since (1) the destination app 935 is not configured to receive the published message 931, and (2) the intermediary computer system 901 will send a message to the destination app in a way which does not require the destination app to be specially adapted to the message.

The processor 905 can be programmed to determine 913 whether the message includes a topic with a registered destination app, when the processor 905 receives a message. For example, the processor can determine whether the topic of the message is included in the container storage 937, using known techniques.

The processor 905 can be programmed to obtain 915 an indication of the registered destination app for the received message. For example, when it is determined that the topic of the message is included in the container storage 937, the processor 905 can access the container storage 937 to retrieve the name(s) of destination apps which are registered for the topic as well as the corresponding property-mapping for the topic and destination app(s).

The processor 905 can be programmed to send 917 the message with the property-mapped destination information to the registered destination app, after performing a property mapping 925 on the information in the message from the source app. The information that was received in the message from the source app 929 is property mapped 925 and then placed into a message 933 to be transmitted to the computer system 935 running the destination app as specified in the container storage 937 for the topic of the received message 931. The message 933 then is transmitted via the transceiver

15

903 from the intermediary computer system 901 to the computer system 935 running the destination app. The message can be transmitted from the computer system 901 to the destination in accordance with known techniques. For example, the destination app can be set to receive data (specific input parameters) from an information providing service, e.g., RSS, using known techniques; the message 933 with the property map information can be sent to the destination app in the same form as the information providing service.

The processor 905 can be programmed to get/send 919 a list of available topics, for example when the processor 905 receives a message via the transceiver 903 with a request for a list of available topics. In response to receiving the message, the processor 905 can retrieve the available topics and corresponding indications of registered destination apps and property mapping (if any) 939, 941, 942. Then, the processor 905 can transmit a message with a response having the list of available topics, for example via the transceiver 903 to the requesting processor, for example, the client 935.

The processor 905 can be programmed to provide 921 a browser interface for the client computer to set up visual wiring of information between the destination app and the source app. The browser interface has been discussed elsewhere herein in detail. The browser interface can be provided to be downloaded to the client computer system, or can be distributed in accordance with known techniques between the client computer system and the intermediary computer system 901, or can principally or entirely on the intermediary computer system 901. When the browser interface to set up wiring is provided at least partly on the client computer system, the intermediary computer system 901 can receiving the wiring parameters (that is, the topic, the source app, the destination app, and the property mapping) from the client computer system via the transceiver 903.

The processor 905 can be programmed to store 923, in the container storage 937, an indication of the destination app as being registered for the topic, with an indication of the selected content fields of the destination app that are to receive information from fields of the source app, together with instructions for mapping the source information to the destination information.

The processor 905 can be programmed to map 925 information from the source app (referred to sometimes as "source information") as specified in the property mapping stored in the container storage 937 for the topic in connection with the destination app, so that the information is in the format expected by the destination app (referred to sometimes as "destination information"). Different ways to map information from a source to a destination are known. For example, information from a source which is provided as two parameters (source (A, B)) and be re-positioned to a destination as two parameters (destination (B, A)); a parameter can be omitted (source (A, B) mapped to destination (B)); and similar. Also, information which is provided as a string can be recast as an integer, or similar. Different ways of mapping information are known and can be used alone or in combination. Accordingly, in one or more embodiments, the mapping includes omitting a portion of the information, recasting at least a portion of the information to a different data-type, extraction of at least a portion of the information, performing a calculation on the information, performing a string manipulation on the information, augmenting the information, so as to conform information that is not compatible as-is from the source app to the content fields displayed at the destination user interface which are to receive the information.

16

It should be understood that FIG. 9 is described in connection with logical groupings of functions or resources. One or more of these logical groupings may be omitted from one or more embodiments. Likewise, functions may be grouped differently, combined, or augmented without parting from the scope. Similarly the present description may describe various databases or collections of data and information. One or more groupings of the data or information may be omitted, distributed, combined, or augmented, or provided locally and/or remotely without departing from the scope.

Referring now to FIG. 10, a flow chart illustrating a process for visual wiring of apps will be discussed and described. The flow chart illustrates parallel flows for a source app procedure 1001, a client procedure 1051, and for sending 1021 information in published messages to apps registered for topics. The client procedure can advantageously be implemented on, for example, a processor of a client computer system, such as described in connection with FIG. 8 or other apparatus appropriately arranged. The procedure for sending 1021 information to apps registered for topics can advantageously be implemented on, for example, a processor of an intermediary computer system, such as described in connection with FIG. 9 or other apparatus appropriately arranged. The source app 1001 procedure conventionally is implemented on a computer system in accordance with known techniques.

The source app 1001 is conventional, and executes a loop in which its information is updated 1003 as usual; and then a message with the updated (or deleted or added) information is published 1005 as usual. A source app can publish limited information, e.g., just a single cell, or much more information. A convenient example is a stock market app that provides stock market quotes, possibly limited to one or several stocks. When one of the stock quotes is updated, then the source app will publish a broadcast message with a topic and with the updated information. Because the source app 1001 is conventional, no further details are provided herein.

Also in overview, the client procedure 1051 initially registers 1053 a destination app for a selected topic along with an indication of the source-to-destination mapping. As discussed above, the registered destination app, topic and source-to-destination mapping are transmitted to a procedure that provides for sending 1021 the requested information to the destination app. The client procedure 1051 also provides for later running 1055 the destination app which was registered; and while the destination app is running, to receive 1057 information as is normal for the destination app and to update the user interface from the received information. While running the destination app, the client procedure loops to continue receiving 1057 information and updating in reaction thereto as usual. Destination apps are conventional, and can receive parameters in a pre-determined format. Destination apps generally do not receive published broadcast messages, because that would require, among other things, subscribing to messages as well as hand-shaking and error checking for the desired messages. An example of an app is a line graphing app, which automatically inserts and displays items (which are received as parameters) in a line chart. Because destination apps 1055, 1057 are conventional, no further details are provided herein.

Reference is now made to the procedure to send 1021 information in published messages to apps registered for topics. The procedure can store 1023 an indication of a registered destination app which has registered for a selected topic, together with an indication of the source-to-destination mapping of information from the source app to the destination app. Also, the procedure can subscribe to receive the topic. Mapping has been discussed previously in detail.

The procedure **1021** can optionally provide **1025** an indication of one or more topics, and for each of the topics, the source app that publishes information about the topic, the destination app(s) registered for the topic, and the property mapping of the source-to-destination information.

Then, the procedure **1021** can receive **1027** a published broadcast message. Because the procedure **1021** can be subscribed to many topics, the procedure checks **1029** whether the published message has a topic with a registered destination app. If not, the published message can be discarded. However, when the published message has a topic with one or more registered destination apps, the procedure will map **1031** the source information included in the published message according to the property-mapping stored with the topic and the indication of the registered destination app. Then the procedure can insert the property-mapped information into a message as parameters in the predetermined format expected by the destination app. Then, the procedure **1021** can send **1033** a message to the destination app, wherein the message has the property-mapped info; the message is sent in a format and/or by a data service that will be recognized by the destination app. Then, the procedure repeats to receive **1027** another published broadcast message and to handle the other received published messages are discussed herein.

The following is a simple example of operation of the illustrated procedure of FIG. **10**. Assume that the source app **1001** is the stock quote app which will provide stock quotes as text for one or more requests stocks. Assume that the destination app is a line graph app and plots a line between numerical data points. The destination app registers **1053** to receive a topic for quotes for one single stock. Then the procedure to send info **1021** to the registered apps stores the indication of the registered destination app for the topic with the indication of the source-to-destination mapping (change text to numerical data); and also subscribes to the topic. The source app may receive updated information from its usual data source, causing the quote for stocks to change, including the single stock for which the topic is subscribed. The source app **1001** updates **1003** its information (as usual), and publishes **1005** a message with the topic (as usual), the message having the updated information for at least the single stock and possibly others. Then, the published broadcast message with the topic is received **1027**. Because a destination app registered for the topic **1029**, the source information in the message is mapped **1031** to the destination information (here, only the content field for the single stock is used and its text is changed to a numerical data point), and a message is sent **1033** with the property-mapped information to the line graph which is the destination app in this example. The line graph destination app receives **1057** the message as usual, the message having the property-mapped information, and displays the data points as usual in the line graph. The stock quote app and the line graph app are unaware of each other; nevertheless information that changes quotes for that stock causes a change in both the source app and the destination app (the line graph app).

If the destination app publishes information, the destination app itself can be a source app for yet another destination app.

The above discussion has involved particular examples. However, the principles apply equally to other examples and/or realizations. Naturally, the relevant data may differ, as appropriate. Further, the above has been discussed in certain examples as if made available by a provider to a single user at a single site. The above described system, device and/or method may be used by numerous users over distributed systems, if preferred.

It should be noted that the term “computer system” used herein denotes a device sometimes referred to as a computer, laptop, main frame computer, personal computer, personal digital assistant, personal assignment pad, notebook computer, notepad computer, smart phone with embedded processor, or equivalents thereof provided such unit is arranged and constructed for operation with an app. As one example, the computer system may be a general purpose computer, or a specially programmed special purpose computer. It may be implemented as a distributed computer system rather than a single computer. Similarly, a communications link may be World Wide Web, a modem over a POTS line, and/or any other wired or wireless method of communicating between computers and/or users. Moreover, the processing could be controlled by a software program on one or more computer system or processors, or could even be partially or wholly implemented in hardware.

Furthermore, the communication networks of interest include those that transmit information in packets, for example, those known as packet switching networks that transmit data in the form of packets, where messages can be packetized and routed over network infrastructure devices to a destination. Such networks include, by way of example, the Internet, intranets, local area networks (LAN), wireless LANs (WLAN), wide area networks (WAN), cellular telephone networks, general packet radio service (GPRS) services, GSM (global system for mobile communications) cellular network, and others, and can be supported by networking protocols such as TCP/IP (Transmission Control Protocol/Internet Protocol) and UDP/UP (Universal Datagram Protocol/Universal Protocol) and/or other protocol structures, and variants and evolutions thereof. Such networks can provide wireless communications capability and/or utilize wireline connections such as cable and/or a connector, or similar. Any appropriate communication protocol may be used.

The term “app” is short for “application,” and denotes a computer executable software program that performs a function to benefit the user; typically the term “app” is used to refer to discrete applications that provide a single function and a simple user interface; an “app” is a way to visualize a mashup; an “app” is different from an operating system that runs the computer. The term “app” is sometimes used to refer to programs such as GoogleMaps.

For the purpose of this patent application, a “mashup” is defined as a software application that combines pre-existing components from one or more information-providing services into a single tool which can comprise a server-side and a client-side application, where the components used by the mashup are visually presented to a user on a display at the client-side in a manner which is different from the pre-determined presentation of the information-providing service; and is configured in accordance with standards such as Enterprise Mashup Markup Language (“EMML”), XML interchanged as REST or Web Services, RSS, Atom, and other evolutions and variations of mashup standards. A mashup is to be distinguished from a portal in which content is presented side-by-side in the manner which is the same as the pre-determined presentation of the information-providing service. The designation “component” as used in this paragraph refers to data which is retrieved by a mashup in real-time from an information-providing service. A mashup is frequently made by access to open APIs and other data sources to produce results that were not the original reason for producing the raw source data. An example of a mashup is the use of cartographic data from Google Maps to add location information to real estate

data, thereby creating a new and distinct Web service that was not originally provided by either source.

The term “service”, sometimes referred to herein as an “information-providing service”, is used herein expressly to refer to an information-providing service that provides data from a server in a visual presentation on a display to a user, typically an application programming interface (API) or web API that can be accessed over a computer network and executed on a remote system hosting the requested services, in accordance with Extensible Markup Language messages that follow the Simple Object Access Protocol (SOAP) standard such as SOAP Version 1.2 specification, Web Services Description Language (WSDL) such as Web Services Description Language Version 2.0 Specification, Representational State Transfer (REST) constraints, and variations and evolutions thereof. An example of a service is Google Maps, a Web service or an RSS feed.

The term “widget” as used herein is defined to be a standalone application which comprises a portable chunk of code that can be installed and executed within a separate HTML-based web page by an end user without requiring additional compilation. A widget frequently is written to use DHTML, JavaScript, or Adobe Flash, variations and evolutions thereof. Widgets often take the form of on-screen tools (clocks, event countdowns, auction-tickers, stock market tickers, flight arrival information, daily weather, etc.).

A computer-readable storage medium is tangible and non-transitory; a computer-readable storage medium can be any of the memory or disks, such as those examples described above, or other removable or fixed storage medium.

One or more displays for the system may be developed in connection with HTML display format. Although HTML is the preferred display format, it is possible to utilize alternative display formats for interacting with a user and obtaining user instructions.

The system used in connection with various embodiments may rely on the integration of various components including, as appropriate and/or if desired, hardware and software servers, applications software, database engines, server area networks, firewall and SSL security, production back-up systems, and/or applications interface software. The configuration may be, preferably, network-based and optionally utilizes the Internet as an exemplary interface with the user for information delivery.

The various databases may be in, for example, a relational database format, but other standard data formats may also be used. Windows 2007, for example, may be used, but other standard operating systems may also be used. Optionally, the various databases include a conversion system capable of receiving data in various standard formats.

The foregoing detailed description includes many specific details. The inclusion of such detail is for the purpose of illustration only and should not be understood to limit the invention. In addition, features in one embodiment may be combined with features in other embodiments of the invention. Various changes may be made without departing from the scope of the invention as defined in the following claims.

This disclosure is intended to explain how to fashion and use various embodiments in accordance with the invention rather than to limit the true, intended, and fair scope and spirit thereof. The invention is defined solely by the appended claims, as they may be amended during the pendency of this application for patent, and all equivalents thereof. The foregoing description is not intended to be exhaustive or to limit the invention to the precise form disclosed. Modifications or variations are possible in light of the above teachings. The embodiment(s) was chosen and described to provide the best

illustration of the principles of the invention and its practical application, and to enable one of ordinary skill in the art to utilize the invention in various embodiments and with various modifications as are suited to the particular use contemplated. All such modifications and variations are within the scope of the invention as determined by the appended claims, as may be amended during the pendency of this application for patent, and all equivalents thereof, when interpreted in accordance with the breadth to which they are fairly, legally, and equitably entitled.

What is claimed is:

1. An intermediary computer system, comprising:

a container storage; and

an intermediary processor cooperatively operable with the container storage, and configured to:

provide, in the container storage, a plurality of registrations, each registration includes:

(i) an indication of a topic among a plurality of topics,

(ii) an indication of a source app, among a plurality of source apps, that publishes, directly to subscribers, information, displayed on a source user interface of the source app, regarding the topic,

(iii) an indication of a destination app registered at the intermediary processor for the topic to receive the information regarding the topic from the intermediary processor, and

(iv) a property mapping indication of how fields in the information published by the source app map to fields in destination information displayed at a destination user interface of the destination app, wherein different registrations in the container storage for a same topic-source app combination support different property mappings for different destination apps;

subscribe, by the intermediary processor, to the topic published by the source app;

receive, in response to the subscription, at the intermediary processor, a published message from the source app, the published message including the information sent from the source app and not property-mapped according to the property mapping in the container storage; and

responsive to receipt of the published message from the source app:

determine, at the intermediary processor, registrations in the container storage which indicate that there is a registered destination app which is registered for the topic in the published message from the source app, and then

for each registration which indicates that there is a registered destination app registered for the topic in the published message from the source app,

property-map the fields in the source information in the published message to the fields in the registered destination app according to the property mapping stored with the topic and the registered destination app in said registration in the container storage, to generate destination information, when it is determined that the registered destination app is registered for the topic in the published message, and then

send, from the intermediary processor, to the registered destination app which is determined to be registered for the topic, the generated destination information which has been property-mapped according to the property mapping in said registration in the container storage, when it is deter-

21

mined that the registered destination app is registered for the topic in the published message, so that publication caused by a change to the information at the source app triggers, via the intermediary processor, a reaction in the destination user interface displaying the information at the destination app, wherein the generated destination information is property-mapped differently for the registered destination app in at least one of the registrations that has the same topic-source app combination, wherein the intermediary processor is configured to facilitate mapping, at the intermediary processor, the information in the published message received from the source app according to the property mapping in the container storage and sending to the destination app a destination message with the information which has been property-mapped as destination information, and

wherein the mapping includes omitting a portion of the information, recasting at least a portion of the information to a different data-type, extraction of at least a portion of the information, performing a calculation on the information, performing a string manipulation on the information, augmenting the information, so as to conform information that is not compatible as-is from the source app to the content fields displayed at the destination user interface which are to receive the information.

2. The intermediary computer system of claim 1, wherein receipt of the message at the intermediary processor and publication of the message from the intermediary processor is performed in accordance with OpenAjax Hub standards.

3. A visual wiring system comprising the intermediary computer system of claim 1 acting as a server, and a client computer system that is running the registered destination app as a client and further that is cooperatively connected to and in communication with the server, the intermediary processor being configured to coordinate receipt by the client of messages from the source app having information for the topic listing the registered destination app stored on the container storage.

4. A computer-implemented method, implemented on a computer system, for visual wiring of apps, comprising:

providing, in a container storage, a plurality of registrations, each registration includes:

- (i) an indication of a topic among a plurality of topics,
- (ii) an indication of a source app, among a plurality of topics, that publishes, directly to subscribers, information, displayed on a source user interface of the source app, regarding the topic,
- (iii) an indication of a destination app registered at an intermediary processor for the topic to receive the information regarding the topic from the intermediary processor, and
- (iv) a property mapping indication of how fields in the information published by the source app map to fields in destination information displayed at a destination user interface of the destination app, wherein different registrations in the container storage for a same topic-source app combination support different property mappings for different destination apps;

subscribing, by the intermediary processor, to the topic published by the source app;

receiving, at the intermediary processor, a published message from the source app, the published message includ-

22

ing the information sent from the source app and not property-mapped according to the property mapping in the container storage; and

responsive to receipt of the published message from the source app:

determining, at the intermediary processor, registrations in the container storage which indicate that there is a registered destination app which is registered for the topic in the published message from the source app, and then

for each registration which indicates that there is a registered destination app registered for the topic in the published message for the source app,

property-mapping the fields in the source information in the published message to the fields in the registered destination app according to the property mapping stored with the topic and the registered destination app in said registration in the container storage, to generate destination information, when it is determined that the registered destination app is registered for the topic in the published message, and then

sending, from the intermediary processor, to the registered destination app which is determined to be registered for the topic, the generated destination information which has been property-mapped according to the property mapping in said registration in the container storage, when it is determined that the registered destination app is registered for the topic in the published message, so that publication caused by a change to the information at the source app triggers, via the intermediary processor, a reaction in the destination user interface displaying the information at the destination app, wherein the generated destination information is property-mapped differently for the registered destination app in at least one of the registrations that has the same topic-source app combination,

the intermediary processor

mapping the information in the published message received from the source app according to the property mapping in the container storage and sending to the destination app a destination message with the information which has been property-mapped as destination information,

wherein the mapping includes omitting a portion of the information, recasting at least a portion of the information to a different data-type, extraction of at least a portion of the information, performing a calculation on the information, performing a string manipulation on the information, augmenting the information, so as to conform information that is not compatible as-is from the source app to the content fields displayed at the destination user interface which are to receive the information.

5. The method of claim 4, further comprising providing a source-destination-browser user interface that simultaneously displays on a single page at a client computer, the destination user interface of the destination app, the source user interface of the source app, and the topic published by the source app;

interacts with a user, via a user input device interface, to selectively indicate on the source-destination-browser user interface (i) content fields displayed in the source user interface from which the information is to be sent and (ii) content fields displayed in the

23

destination user interface which are to receive the information from the content fields in the source user interface; and

storing, in the registration in the container storage, an indication of the destination app as being registered for the topic together with an indication of the selected content fields of the destination app which are to receive the information from the selected content fields of the source app, whereby the source app and the destination app do not need to be known to each other and are wired together at the registration in the container storage.

6. The method of claim 4, wherein receipt of the message at the intermediary processor and publication of the message from the intermediary processor is performed in accordance with OpenAjax Hub standards.

7. The method of claim 4, further comprising providing a source-destination-browser user interface that simultaneously displays on a single page a plurality of topics published by the source app, each of the topics are published, each of the topics a source app, and interacts with a user to select at least one destination app to register for at least one of the plurality of topics.

8. The method of claim 4, further comprising providing a source-destination-browser user interface that simultaneously displays on a single page a plurality of topics which are published each having a source app and at least one registered destination app, and interacts with a user to select one or more of the topics to be disabled from publishing.

9. A non-transitory computer-readable medium storing instructions for executing the method of claim 4.

10. A non-transitory computer-readable medium comprising instructions for execution by a computer, the instructions including a computer-implemented method for visual wiring of apps, the instructions for implementing:

- providing, in a container storage, a plurality of registrations, each registration includes:
 - (i) an indication of a topic among a plurality of topics,
 - (ii) an indication of a source app, among a plurality of source apps, that publishes, directly to subscribers, information, displayed on a source user interface of the source app, regarding the topic,
 - (iii) an indication of a destination app registered at an intermediary processor for the topic to receive the information regarding the topic from the intermediary processor, and
 - (iv) a property mapping indication of how fields in the information published by the source app map to fields in destination information displayed at a destination user interface of the destination app,

wherein different registrations in the container storage for a same topic-source app combination support different property mappings for different destination apps;

subscribing, by the intermediary processor, to the topic published by the source app;

receiving, in response to the subscription, at the intermediary processor, a published message from the source app, the published message including the information sent from the source app and not property-mapped according to the property mapping in the container storage; and

responsive to receipt of the published message from the source app:

- determining, at the intermediary processor, registrations in the container storage which indicate that there is a

24

registered destination app which is registered for the topic in the published message from the source app, and then

for each registration which indicates that there is a registered destination app registered for the topic in the published message from the source app,

- property-mapping the fields in the source information in the published message to the fields in the registered destination app according to the property mapping stored with the topic and the registered destination app in said registration in the container storage, to generate destination information, when it is determined that the registered destination app is registered for the topic in the published message, and then
- sending, from the intermediary processor, to the registered destination app which is determined to be registered for the topic, the generated destination information which has been property-mapped according to the property mapping in said registration in the container storage, when it is determined that the registered destination app is registered for the topic in the published message, so that publication caused by a change to the information at the source app triggers, via the intermediary processor, a reaction in the destination user interface displaying the information at the destination app, wherein the generated destination information is property-mapped differently for the registered destination app in at least one of the registrations that has the same topic-source app combination, and

the intermediary processor

- mapping the information in the published message received from the source app according to the property mapping in the container storage and
- sending to the destination app a destination message with the information which has been property-mapped as destination information,

wherein the mapping includes omitting a portion of the information, recasting at least a portion of the information to a different data-type, extraction of at least a portion of the information, performing a calculation on the information, performing a string manipulation on the information, augmenting the information, so as to conform information that is not compatible as-is from the source app to the content fields displayed at the destination user interface which are to receive the information.

11. The computer-readable medium of claim 10, further comprising instructions for:

- providing a source-destination-browser user interface that simultaneously displays on a single page at a client computer, the destination user interface of the destination app, the source user interface of the source app, and the topic published by the source app;
- interacts with a user, via a user input device interface, to selectively indicate on the source-destination-browser user interface (i) content fields displayed in the source user interface from which the information is to be sent and (ii) content fields displayed in the destination user interface which are to receive the information from the content fields in the source user interface; and
- storing, in the registration in the container storage, an indication of the destination app as being registered for the topic together with an indication of the selected content fields of the destination app which are to receive the information from the selected content fields of the

25

source app, whereby the source app and the destination app do not need to be known to each other and are wired together at the registration in the container storage.

12. The computer-readable medium of claim 11, wherein receipt of the message at the intermediary processor and publication of the message from the intermediary processor is performed in accordance with OpenAjax Hub standards. 5

13. The computer-readable medium of claim 11, further comprising instructions for:

providing the source-destination-browser user interface 10 that

simultaneously displays on a single page a plurality of topics published by the source app, each of the topics are published, each of the topics having a source app, and 15

interacts with a user to select at least one destination app to register for at least one of the plurality of topics.

14. The computer-readable medium of claim 11, further comprising instructions for

providing the source-destination-browser user interface 20 that

simultaneously displays on a single page a plurality of topics published by the source app, each of the topics are published, each of the topics having a source app and at least one registered destination app, and 25

interacts with a user to select one or more of the topics to be disabled from publishing.
